GAP Care Pathway (Phase I)
Risk assessment, surveillance, investigation and management
TO BE USED IN CONJUNCTION WITH EXPLANATORY NOTES

### Risk assessment
- **Low Risk**
  - Serial standardised fundal height (SFH) measurements plotted on GROW chart from 26-28 weeks 2-3 weekly until delivery
  - Fist SFH <10th centile or slow / static growth
  - USS EFW, LV, UAD as required

### Fetal growth surveillance
- Regular SFH measurements
- First SFH <10th centile or slow / static growth
- USS EFW, LV, UAD as required

### Further investigation and management
- Serial scan EFWs plotted on GROW chart from 28 weeks, 3 weekly until delivery
- EFWs <10th centile or slow / static growth
- Additional UAD as required

### Timing of Delivery
- **Expectant Management**
- **First SFH <10th centile or Slow / static growth**
  - Suitabe for Consultant led care
  - Obstetric review to determine level of risk
  - Fetal Medicine review
  - UtA Doppler 20-23 weeks
  - Serial scan EFWs plotted on GROW chart from 24-28 weeks, 2-4 weekly until delivery

### Investigations
- **Normal**
- **Abnormal**

### Unsuitable for SFH
- BMI ≥35
- Large or multiple Fibroids

### Increased Risk
- Maternal age ≥40
- Smoker (any)
- Drug misuse
- Medical history
- Cyst-SGA/FGR
- PET, HT, Stillbirth
- Current pregnancy
- PAPP A <5th centile
- Echogenic bowel
- Significant bleeding

### Abbreviations:
- AID= Autoimmune Disease; APLS= Antiphospholipid Syndrome; BMI= Body Mass Index; CHD= Coronary Heart Disease; EFW= Estimated Fetal Weight; FGR= Fetal Growth Restriction; SFH= Standardised Fundal Height; HT= Hypertension; LV= Liquor Volume; PET= Pre-eclampsia; SGA= small for gestational age; SLE= systemic lupus erythematosus; UAD= Umbilical Artery Dopplers: UtA = Uterine Artery Doppler. See ‘GAP Care Pathway v2 - Explanatory Notes’
GAP Care Pathway (Phase II)
Risk assessment, surveillance, investigation and management
TO BE USED IN CONJUNCTION WITH EXPLANATORY NOTES

Risk assessment  
Fetal growth surveillance  
Further investigation and management  
Timing of Delivery

Low Risk
- Serial standardised fundal height (SFH) measurements plotted on GROW chart from 26-28 weeks 2-3 weekly until delivery
- Regular SFH measurements
- First SFH <10th centile or slow / static growth
  - USS EFW, LV, UAD as required
  - EFW >10th centile with normal growth velocity and normal Dopplers
  - EFW <3rd centile, or slow/static growth, or abnormal UAD, UtA or MCA/CPR

Unsuitable for SFH
- BMI ≥35
- Large or multiple fibroids

Increased Risk
- Maternal age ≥40
- Smoker (any)
- Drug misuse
- Medical history
  - HT, AID (SLE, APLS), Cyanotic CHD, Kidney D
- Obstetric history
  - Cust-SGA/FGR, PET, HT, Stillbirth
- Current pregnancy
  - PAPP A <5th centile
- Echogenic bowel
- Significant bleeding

Suitable for Consultant led care
- Moderate risk
- Obstetric review to determine level of risk
- UTA Doppler 20-23 weeks

Fetal Medicine Surveillance
- Serial scan EFWs plotted on GROW chart from 24-28 weeks, 2-4 weekly until delivery
- <32w
- Fetal Medicine Investigations
- Plan of care Management

Abbreviations: AID= Autoimmune Disease; APLS= Antiphospholipid Syndrome; BMI= Body Mass Index; CHD= Coronary Heart Disease; CPR= Cerebro-Placental Ratio; EFW= Estimated Fetal Weight; FGR= Fetal Growth Restriction; SFH= Standardised Fundal Height; HT= Hypertension; LV= Liquor Volume; MCA = Middle Cerebral Artery; PET= Pre-eclampsia; SGA= small for gestational age; SLE= systemic lupus erythematosus; UAD= Umbilical Artery Dopplers; UtA = Uterine Artery Doppler. See ‘GAP Care Pathway v2 - Explanatory Notes’
Introduction

Following publication of NHS England’s Saving Babies’ Lives Care Bundle version 2 (CBv2) last year [1], the Perinatal Institute has undertaken consultations on how to align and adapt it for NHS Trusts in the GAP programme, while maintaining the benefits of a tried and tested protocol that has been credited as a main factor in the recent reduction of stillbirth rates in England [2, 3, 4].

Our new care pathway seeks to balance the need to identify, investigate and appropriately manage at-risk pregnancies with the aim to avoid unnecessary intervention. It continues the emphasis on surveillance according to risk assessment, by standardised fundal height (SFH) and estimated fetal weight (EFW) measurements, serially plotted on customised charts to improve the distinction between constitutional and pathological smallness [5, 6, 7, 8, 9]. A focus of the revised pathway is a new, evidence-based definition of slow growth (see Section B).

Concerns about the ultrasound and Doppler capacity demands of CBv2, expressed at the 2019 National GAP User Symposium, have since been confirmed by a survey we conducted in association with the British Medical Ultrasound Society (BMUS), which showed that most ultrasound services in the NHS cannot currently meet the requirements [9]. The Society of Radiographers have also expressed concern [10].

We have therefore developed a Care Pathway which can be implemented in two phases, according to Trust capacity. Phase I should be achievable with current resources, while sonographic services seek to acquire the additional training and resources required for Phase II. These Explanatory Notes are designed to be read in conjunction with Care Pathway algorithms I and II.

While we have made these recommendations as evidence-based as possible, maternity care needs to be personalised and based on good clinical judgement. The Perinatal Institute and its staff cannot be held liable for any adverse outcome.

A. Risk Assessment

1. Early pregnancy risk assessment and triage into the correct care pathway is essential. As the significance of risk factors is often determined by the severity of current and previous conditions and various other circumstances, moderate and high risk categories are amalgamated into an ‘Increased risk’ group, which should undergo obstetric review to help determine the appropriate pathway and level required for investigations and surveillance.

2. Pre-existing diabetes, diabetes arising during pregnancy, or multifetal pregnancy are covered by their respective NICE guidelines and are out of scope of this document.

3. Previous ‘SGA’, if determined by customised centiles, is more likely to be due to fetal growth restriction (FGR) than if SGA is determined by population centiles (on which CBv2 is based). It is therefore more likely to represent high risk and is often the only available indicator of the likelihood that there was indeed previous FGR. Obstetric review should consider severity, gestational age at onset (if known), gestational age at delivery and associated factors such as preeclampsia.
4. Previous stillbirth is considered an increased risk, regardless of size and stated cause, unless placental insufficiency has been reliably excluded by placental pathology examination.

5. Calculating an estimated fetal weight (EFW) at the time of the anomaly scan is not recommended, as good evidence is lacking about its efficacy to predict adverse outcome. Preliminary results presented at the 2019 Fetal Growth conference [11] suggest that the narrow normal range at 20-23 weeks can frequently lead to a false positive suspicion of SGA. The error is substantially increased with population based fetal weight standards. If units nevertheless wish to assess EFW at this time, we recommend to use the customised centile calculator which works from 20 weeks gestation and is available from the GAP Team on request.

6. For women with a history of, or significant risk factor for, placental dysfunction (including history of pre-eclampsia or fetal growth restriction), **Aspirin 75-150mg nocte** is recommended from 12 weeks to birth according to the latest NICE guidelines [12].

7. The recommended initial obstetric review of pregnancies considered at increased risk should determine next steps according to severity and unit policy.

   **Phase 1:** Pregnancies considered high risk should be referred to maternal-fetal medicine (MFM) services, where available, for investigation and review:
   - if uterine artery (UtA) Doppler normal ➔ moderate risk pathway;
   - if UtA Doppler abnormal – continue under MFM surveillance

   Where MFM services are not available, frequent assessment from 24 weeks throughout the third trimester is recommended, as per Care Pathway.

   **Phase 2:** Pregnancies considered high risk can have UtA Doppler performed in the ultrasound department, with referral to MFM if abnormal.

### B. Fetal growth surveillance

1. The **low risk pathway** follows the existing algorithm, with 2-3 weekly clinical assessment and fundal height measurement from 26-28 weeks until delivery, according to unit policy, using a standardised technique [13] and with measurements plotted on the customised GROW chart. If suboptimal growth is suspected (first fundal height measurement <10th centile; or slow or static growth), direct referral for growth scan and Doppler is recommended. If resources permit, a scan EFW should be repeated in 3 weeks time to ascertain velocity, as a single scan cannot provide reassurance about the growth trajectory of the fetus (see B4).

2. **Where SFH is unreliable** because of high BMI (35+) or large or multiple fibroids [6], growth monitoring by serial ultrasound scan is indicated. Where resources allow, this should be done 3 weekly and, where resources permit, starting from **28 weeks** (rather than 32), as an EFW at this gestational age serves as an important baseline for assessment of fetal growth in the third trimester.

3. **Normal growth rate / velocity** varies with gestational age and is highest in the middle of the third trimester. It also varies with the customised growth potential of each fetus. For example, the average (50th centile) velocity, expressed in grams per day (g/d), can range from 22g/d between 28-31 weeks in a small mother with a baby of expected term weight of 3100g, to 32g/d between 34-37 weeks for a larger mother expecting a baby weighing 3700 g (= 50% higher). Similarly, the 10th and 3rd centile growth rates shown on the GROW chart also vary with gestational age and expected birthweight.

4. Slow or static growth by **serial SFHs** is defined as a trajectory which is less (slower) than the slope of the curve / growth velocity indicated by the **10th centile line** on the customised chart **over the same gestational age interval**. The 10th centile is the appropriately sensitive screening tool to identify cases that need referral for ultrasound biometry.
5. Slow or static growth by serial EFWs is defined as a trajectory between scan measurements which is slower than the slope of the 3rd centile line on the customised chart over the same gestational age interval. A growth rate less than the slope of the customised 3rd centile line predicts adverse perinatal outcome [14]. For precision and reduced effect of scan error, routine serial EFW measurements to assess growth velocity should be at least 3 weeks apart [7]. While third trimester EFW measurements in routine NHS practice have been shown to be accurate to within +/-10% in 70% of cases [15], consideration should be given to the clinical implication of potential scan error, as well as the overall need for quality assurance. The Perinatal Institute has developed a free audit tool for EFW error, available from the GAP team.

6. During 2020, we will be introducing auto-plotting and digital assessment in the new GROW App, with alerts if the growth velocity is outside the normal range at the respective stage in pregnancy. In the interim, visual assessment is required, comparing serial SFH and EFW measurements with the 10th and 3rd centile reference lines. Plotting can be assisted by set-squares, available from the GAP Team. The figures below illustrate an example of manual assessment of growth rate:

![Fig 1](left) has two sample EFW measurements plotted at 36 and 39 weeks. The two measurement each lie between the 50th and 90th centile but taken in sequence, they suggest slow growth. This is confirmed in Fig 2 (right), where a line is drawn through the two plots to delineate the slope. Using a set square, a parallel line is drawn through the 3rd centile line over the same gestational age interval; this shows that the growth rate is slower than the lowest accepted rate in this pregnancy, over this gestation interval. The use of a set square to draw parallel lines is illustrated in a short video clip available [here](#).

### C. Further Investigation and Management

1. The Care Pathway outlines the suggested level of surveillance when placental insufficiency is suspected - by an EFW <10th centile, or slow or static growth, with or without abnormal Dopplers. Fetal medicine involvement should be sought at early gestations, e.g. before 32-34 weeks.

2. In pregnancies with evidence of growth restriction (EFW<3rd centile and/or slow or static growth and/or abnormal Dopplers), delivery will be indicated by 37.0 weeks or earlier, according to severity and Doppler findings. If growth velocity and Dopplers are normal, an EFW <3rd centile should still be considered FGR and the baby delivered before the end of 37 completed weeks (37 weeks 6 days).

3. An EFW between the 3rd and 10th centile, on a customised chart adjusted for constitutional variation, is also associated with increased risk of adverse perinatal outcome if the pregnancy continues to
Concern about early term delivery because of an association with special educational needs (SEN) in infancy and childhood [16] needs to be balanced by the significantly increased cerebral palsy risk in SGA babies delivered at term [17]. Furthermore, there risk of stillbirth is also increased; the majority of deaths prevented since the introduction of GAP had late onset FGR in the 3rd to 10th centile band [18]. Consideration of timing of delivery should include uterine and middle cerebral artery Doppler findings: if all Dopplers are normal, expectant management to 39 weeks is likely to be safe [19]. When such investigations are not available and growth restriction cannot be excluded (Phase I), earlier delivery is advisable, as indicated in the algorithm.

### D. Audit

Ongoing audit of detection rates is essential to monitor progress. The GROW App will produce the following reports to assist units – quarterly or half yearly, depending on the size of the service:

1. Proportion of babies born <10th and <3rd centile
2. Antenatal detection rates of babies born <10th and <3rd centile
3. False positive detection rates of babies born <10th and <3rd centile

The reports will also include a national average comparison and a top 10-unit comparison. With approval of participating units, reports can also be produced for networks and regions.

Optional questions will be added in the GROW App in 2020 to enable units to undertake more thorough assessment of service provided and outcome achieved. These will include:

- Proportion of pregnancies identified as increased risk in early pregnancy, and care offered
- Aspirin use and outcome
- Third trimester scan regime and outcome, according to risk factors

In addition, the GAP-SCORE tool will facilitate ongoing case-note review of ‘missed’ SGA (neonates with birthweight <10th and <3rd centile) and reasons why they were not detected antenatally.

### Conclusion

The new GAP Care Pathway introduces the main recommendations of version 2 of the Care Bundle while retaining and building on the key elements of the successful GAP algorithm and customised surveillance. The Care Pathway is presented in two phases, with Phase I for interim use while fulfilling the training and resource requirements to be able to deliver Phase II.

### Next steps

2. The regular, free on-site GAP training workshops will focus on new GAP Care Pathway. To register: [www.perinatal.org.uk/diary/gapbookingform.aspx](http://www.perinatal.org.uk/diary/gapbookingform.aspx)
3. We are developing e-learning and certification courses for sonographers – details to be announced.
4. We are working with BMUS and SOR to address training and resource needs associated with CBv2.
